

Chapter 2: Algebraic Expressions & Exponents

ALGEBRAIC EXPRESSIONS

Addition and Subtraction

Only like terms can be added or subtracted. Like terms have the same variable and exponent on the variable (e.g. 10, 5, and 2 are like terms; x , $3x$, and $5x$ are like terms; $5x^2$ and $2x^2$ are like terms.) To combine like terms: add or subtract the numerical coefficients and keep the variable part the same. No numerical coefficient in front of the variable means a coefficient of 1.

$$\begin{aligned} 3x + 3 + 4x + x & \dots\dots\dots \text{the three terms with } x\text{'s are like terms} \\ = (3 + 4 + 1)x + 3 & \dots\dots\dots \text{add the numerical coefficients of the like terms} \\ = 8x + 3 \end{aligned}$$

Simplification involving brackets. To remove the brackets, use the following rules:

- (+) sign or no sign in front of the brackets: drop the brackets and copy the terms inside the brackets with signs unchanged. $(-7a + 5b - c)$ becomes $-7a + 5b - c$
- (-) sign in front of the brackets: drop the brackets and change the sign of every term inside the brackets. $-(-7a + 5b - c)$ becomes $7a - 5b + c$

Multiplication and Division

- To find the product of two or more single terms (monomials), find the product of the numerical coefficients and multiply by the product of their variables.

$$\begin{aligned} 5a(2b) & \\ = (5 \times 2)(a \times b) & \dots\dots\dots \text{obtain the products of the numerical coefficients and the variables} \\ = 10 \times b^2 = 10b^2 \end{aligned}$$

- To find the product of a polynomial (multiple terms) and a monomial, multiply each term of the polynomial by the monomial.

$$\begin{aligned} -2a(5a - 3b) & \\ = (-2a)(5a) - (-2a)(3b) & \dots\dots\dots \text{multiply each term by } (-2a) \\ = -10a^2 + 6ab \end{aligned}$$

- To find the product of two polynomials, multiply each term of the first polynomial by each term of the other polynomial and then simplify by combining like terms.

$$\begin{aligned} (a + 2)(2a - 3) & \dots\dots\dots \text{each term of the first polynomial is multiplied} \\ = a(2a - 3) + 2(2a - 3) & \dots\dots\dots \text{by the second polynomial} \\ = 2a^2 - 3a + 4a - 6 & \dots\dots\dots \text{carry out the multiplication} \\ = 2a^2 + a - 6 & \dots\dots\dots \text{simplify} \end{aligned}$$

- To divide monomials, divide the numerical coefficients and the variables separately. Then multiply the answers.

$$12ab \div 6a = \left(\frac{12}{6}\right) \left(\frac{ab}{a}\right) = 2a$$

- To divide a polynomial by a monomial, divide each term of the polynomial by the monomial.

$$(12a + 8) \div 4 = \frac{12a + 8}{4} = \frac{12a}{4} + \frac{8}{4} = 3a + 2$$
