
The Periodic Table arranges the chemical elements in two ways. The first is by **atomic number,** starting with hydrogen (atomic number =1) in the upper left-hand corner and continuing in ascending order from left to right. The second is by the number of electrons in the outermost shell. Elements having the same number of electrons in the outermost shell are placed in the same column. Since the number of electrons in the outermost shell in large part determines the chemical nature of an element, elements in the same column have similar chemical properties.

This arrangement of the elements was devised by **Dmitri Mendeleev** in 1869, before many of the elements now known were discovered. To maintain the overall logic of the table, Mendeleev allowed space for undiscovered elements whose existence he predicted. This space has since been partly filled in, most recently by the addition of elements 104–115. Elements 111–115 have been isolated experimentally but not yet officially named.

The **lanthanide** series (elements 57–71) and the **actinide** series (elements 89–103) are composed of elements with Group 3b chemical properties. They are placed below the main body of the table to make it easier to read.
