## **QUANTUM MECHANICS WORKSHEET**

- In Bohr's theory of the atom, the energy levels of an atom are said to be "quantized". What is meant by the term quantum of energy?
- Both the Bohr model and the quantum mechanical model of the atom involve quantized energy levels for electrons. 2. How are the models different in their description of electron location?
- Define Heisenberg's uncertainty principle.
- Define the term atomic orbital.
- Sketch the shapes of the s, p, and d orbitals.
- Name the 4 quantum numbers how are they designated, what information do they provide
- 6. 7. Answer the following:
  - How many s-orbitals are there at any principal energy level?
  - How are s-orbitals designated for each level? b)
  - At which energy level do p-orbitals first appear? c)
  - How many p-orbitals are present for each level? How is the orientation of the p-orbital indicated? d)
  - e)
  - At which level do d-orbitals first appear?
- How many d-orbitals are present at each level?
- a) What is the relationship between the principal energy level (n) and the number of orbitals found at that level?
  - What is the maximum number of electrons allowed in any orbital?
  - How do you determine the number of orientations for a particular orbital? What does  $2n^2$  stand for?
  - d)
  - How many subshells are available in the 4<sup>th</sup> energy level? How many orbitals are present in each of the subshells? Name each of the orbitals.
    Why does the M shell in Bohr theory really contain 18 electrons while the N shell really contains 32 electrons?
- Define the following.
  - a) Aufbau Principle Hund's Rule
  - b)
  - Pauli's Exclusion Principle
- 10. Write the orbital filling and electron configurations of the first 20 elements.

  11. Write the electron configurations of the following:
- - selenium
  - b) vanadium
  - chromium c)
  - d) nickel
  - e) copper
  - strontium
